

## Growth Arithmetic -- "hat rules" --

$\hat{\phantom{x}}$  over a variable denotes the **growth** of the variable (continuous compound growth<sup>1</sup>);

1.  $\hat{X} = \ln(X_{\text{end}}/X_{\text{start}})$

from 100 to 102?  $\ln(1.02) \approx .0198$  or 1.98% – or about 2%

100 to 105? 4.88% or 4.9% or 5%

\* when growth is small, it is about the same as percentage change

100 to 150?	150 to 100	
+40.55%	-40.55%	total growth 0

<b>% changes?</b>	+50%	-33.3%	total change is zero, so +50% - 33.3% = 0 yech!
-------------------	------	--------	---

2. average annual growth rate  $\text{agr} = \hat{X} / \# \text{years}$  -- simply growth averaged over the number of years.

pcGDP 1900 to 2000 (2009\$) \$6,004 \$ 44,475 7.4 times as much in 100 years ...  
 $\ln(44,475/6004) = 2.003$  growth of 2.003 in 100 years, average of 2.00 % per year ....

3. doubling is **69.3%** growth –  $\ln(2) \approx 0.693$  Re-arrange  $\hat{X} = \text{agr} * t$  And time to double =  $69.3\% / \text{agr}$

1% vs 3% vs 5% : 5 times as fast, takes 1/5 as long to achieve a growth ... doubling is 69.3% growth

Growth at 5% per year doubles in just under 14 years ( $5 * 14 = 70$ , just over 69.3).

20th C US pcGDP averaged 2 % per year, so doubled every 35 ... quadrupled in a lifetime ...

4. growth of per capita output if output and pop both grow 2%? 0 ... subtract

if  $c = a * b$  then  $\hat{c} = \hat{a} + \hat{b}$  and  $\hat{c} - \hat{a} = \hat{b}$  and  $\hat{c}/\hat{a} = \hat{b}$

thus **pcGDP<sup>^</sup>** = GDP<sup>^</sup> - Pop<sup>^</sup>

productivity ( $\rho$ ) is defined as the ratio of output to input ( $y/z$ ).  
Measured productivity  $\text{TFP} = \text{GDP}/Z$  (total factor productivity)

Re-arrange to show that we can think of output as a product of two things  $\text{GDP} = ? Z * \text{TFP} \dots$   
Next step:  $\text{pcGDP} = ? (Z/\text{Pop}) * \text{TFP}$  Growths?  $\text{pcGDP}^{\wedge} = (Z/\text{Pop})^{\wedge} + \text{TFP}^{\wedge}$  Finally,  
growths?  $\text{pcy}^{\wedge} = (z/\text{Pop})^{\wedge} + \text{TFP}^{\wedge}$

use model to interpret data on output and inputs –  $\text{pcGDP}^{\wedge} = \text{pcZ}^{\wedge} + \text{TFP}^{\wedge}$

---

1 the underlying model is  $X_t = X_0 e^{rt}$
